Privacy threat analysis

Mina Deng, <u>Kim Wuyts</u>, <u>Riccardo Scandariato</u>, Bart Preneel, Wouter Joosen

Objectives

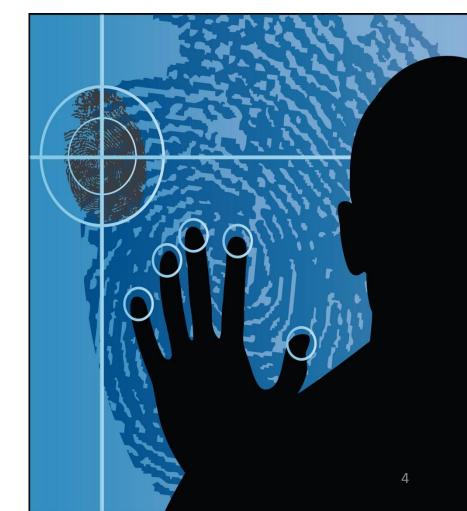

- Understanding the nature of privacy requirements and their relationship with antirequirements
- Method to elicit privacy anti-requirements (LINDDUN)
- Documenting privacy threats

Overview

- Privacy
 - What?
 - Properties
 - Privacy methodology
 - Example case study
 - Project information

Privacy

- what is privacy?
 - Confidentiality
 - Data minimization
 - User empowerment

What is privacy?

- The right to be let alone (Warren & Brandeis, 1890)
- The right of the individual to decide what information about himself should be communicated to others and under what circumstances (*Westin, 1970*)
- Freedom from unreasonable constraints on the construction of one's own identity (*Agre & Rotenberg, 2001*)

People don't care about online privacy?

- In the "real world": concerned about information we share
 - Who they tell what
 - You might be willing to tell your best friend that you had an argument with your girlfriend, but you don't want everybody to know about it
 - Concerns over information taken out of context
 - A picture taken at a crazy party being available to a potential employer
 - We value friends who are discreet and keep our secrets
 - We give more information to people we trust
 - The cost of gathering and analyzing information without advanced technologies has guaranteed that we had a rather high level of privacy protection

People don't care about online privacy?

- Online:
 - less concerned or unaware of privacy violations
- This information is not necessarily secret, but would you want to broadcast it?
 - Identity attributes (Name, age, gender, race, IQ, marital status, place of birth, address, phone number, ID number...)
 - Location (Where you are at a certain point in time, movement patterns)
 - Interests / preferences (Books you read, music you listen, films you like, sports you practice, political affiliation, religious beliefs, sexual orientation)
 - Behavior (Personality type, what you eat, what you shop, how you behave and interact with others)
 - Social network (Who your friends are, who you meet when, your different social circles)
 - Health data (Medical issues, treatments you follow, DNA, health risk factors)
 - Financial data (How much you earn, how you spend your money, credit card number, bank account)
- Combination of them all is even more troublesome

Privacy problems

- Identity theft
 - Getting a credit card on your name
- Stalking
- Profiling
 - Find compulsive buyers, ...
- Sensitive information being shared

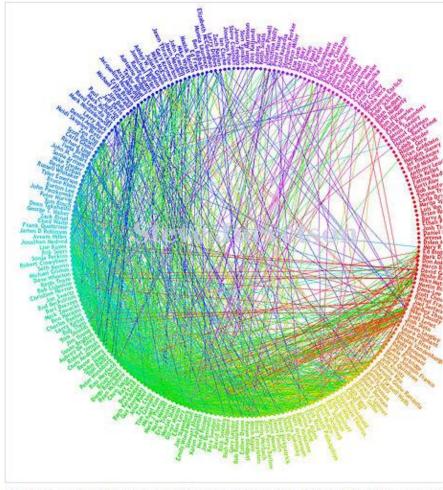

Signs of the social networking times.

• Information taken out of context

Gaydar Algorithm Outs Facebook Users

By Susannah F. Locke Posted 09.21.2009 at 12:27 pm 📃 12 Comments

What are your friends saying about you? Online social networks like this Facebook one mi sharing things you'd rather keep to yourself. Even if more about you than you think *jurvetson (CC licensed)* you're only declaring to the world that someone's you're only declaring to the world that you're only declaring to the world th

A pair of MIT students claim that they have created an algorithm that outs gay members of Facebook by analyzing the sexual orientations of their networks of friends.

The students first analyzed the networks of people who publicized their sexual orientation on Facebook. Turns out that statistically speaking, gay men have more gay friends than straight guys do. So then, they used an algorithm to run the stats on men who kept mum about their sexual orientation on the site. Their computer program was able to correctly identify 10 men whom the students personally knew to be gay in the real world but who hadn't shared that fact on Facebook. (The algorithm didn't work as well with women or with bisexual Facebookers.)

The students completed the project for a class on ethics and the Internet and hope to publish it in a scientific journal.

Their project is far from the first study showing that a simple computer program can sleuth out details you might prefer to keep private by looking at your social network on the Internet. Earlier this year, computer scientists correctly linked 30 percent of anonymous Twitter and Flickr accounts with a simple algorithm that compares who's following who on each site. And other researchers have used Internet social networks to correctly identify peoples' political affiliations or where they live.

It's a good reminder to take a look at your privacy settings. Because you might inadvertently be sharing things you'd rather keep to yourself. Even if you're only declaring to the world that someone's your friend.

'I'm going to destroy America and dig up Marilyn Monroe': British pair arrested in U.S. on terror charges over Twitter jokes

By RICHARD HARTLEY-PARKINSON

Last updated at 1:08 PM on 31st January 2012

Comments (1089) Share

Two British tourists were barred from entering America after joking on Twitter that they were going to 'destroy America' and 'dig up Marilyn Monroe'.

Leigh Van Bryan, 26, was handcuffed and kept under armed guard in a cell with Mexican drug dealers for 12 hours after landing in Los Angeles with pal Emily Bunting.

The Department of Homeland Security flagged him as a potential threat when he posted an excited tweet to his pals about his forthcoming trip to Hollywood which read: 'Free this week, for quick gossip/prep before I go and destroy America?'

Spear-phishing

Using personal information to make phishing more successful

Dear 'cs.kuleuven.be' E-mail User,

We are currently upgrading our database and all account need to be verified. To complete your account activation with us, you are required to reply to this message and enter your password in the space provided (******) you are required to do this before the next 48 hours of the receipt of this email or your database will be de-activated from our database.

Full Name: username: Password: Thank you for using cs.kuleuven.be Copyright 2012 © cs.kuleuven.be web Team.

Using Facebook data

Freddi Staur

- 41% agreed to be friends with Freddi which (often) led to access to
 - Email address
 - Full date of birth
 - Details on education and workplace
 - Current address
 - Pictures of family and friends
 - Name of their partner / relatives

Privacy properties

- Unlinkability
- Anonymity/ pseudonymity
- Plausible deniability
- Undetectability
- Confidentiality
- Content awareness
- Policy and consent compliance

Hard privacy

Security

Soft privacy

Hard privacy

- Data minimization
 - Subject provides as little data as possible
 - Reduce as much as possible the need to "trust" other entities

Soft privacy

- Data subject has already lost control of her data
 - In practice, very difficult for data subject to verify how her data are collected and processed

Soft privacy

Need to trust data controllers (honesty, competence)

Privacy

Anonymity & Pseudonymity

Anonymity

An attacker cannot sufficiently identify the subject within a set of subjects, the anonymity set

Anonymity

- An attacker cannot sufficiently identify the subject within a set of subjects, the anonymity set (Pfitzmann)
- Hiding link between identity and action / piece of information.
- Examples:

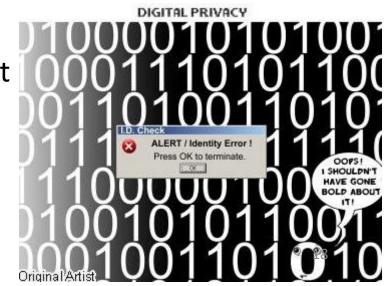

Reader of a web page, person
 accessing a service

Sender of an email, writer of a text

 \circ Person to whom an entry in a

database relates

 Person present in a physical location

Anonymity set

Anonymity set wrt attacker

Identifiability

- The attacker can sufficiently identify the subject within a set of subjects, the identifiability set (pfitzmann)
- A identity is any subset of attribute values of an individual personal which sufficiently identifies this individual person with any set of persons.
 - There can thus be many "identities"

Identifiability example

• Browser uniqueness

Your browser fingerprint appears to be unique among the 2,123,272 tested so far.

Currently, we estimate that your browser has a fingerprint that conveys at least 21.02 bits of identifying information.

The measurements we used to obtain this result are listed below. You can read more about our methodology, statistical results, and some defenses against fingerprinting in this article.

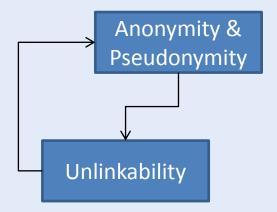

http://panopticlick.eff.org/

Possible to track "anonymous" visitors

Pseudonymity

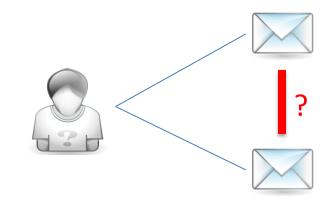

- A pseudonym is an identifier of a subject other than one of the subjects real names.
 Pseudonymity is the use of pseudonyms as identifiers. (Pfitzmann)
- Pseudonymity is the entire field between anonymity and identifiability

Privacy

Unlinkability

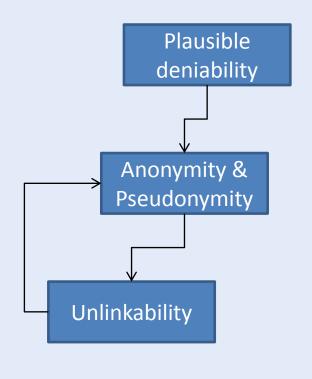

Within a system, the attacker cannot sufficiently distinguish whether two or more items of interest (IOI) are related or not

Unlinkability

- Within a system, the attacker cannot sufficiently distinguish whether two or more items of interest (IOI) are related or not (Pfitzman)
- Hiding link between two or more actions / identities /pieces of information
- Examples:
 - Two anonymous letters written by the same person
 - Two web page visits by the same user
 - Entries in two databases related to the same person
 - Two people related by a friendship link
 - Same person spotted in two locations at different points in time

Privacy

Plausible deniability

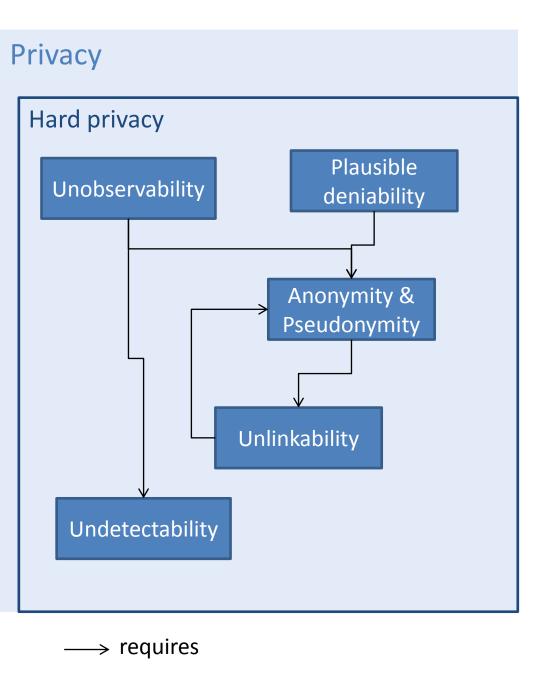

Not possible to prove user knows, has done or has said something

Plausible deniability

- Not possible to prove user knows, has done or has said something
- Examples:
 - Resistance to coercion:
 - Not possible to prove that a person has hidden information in a computer
 - Not possible to know that someone has the combination of a safe
 - Possibility to deny having been in a place at a certain point in time
 - Possibility to deny that a database record belongs to a person
 - Off-the-record conversations

Undetectability

The attacker cannot sufficiently distinguish whether it exists or not

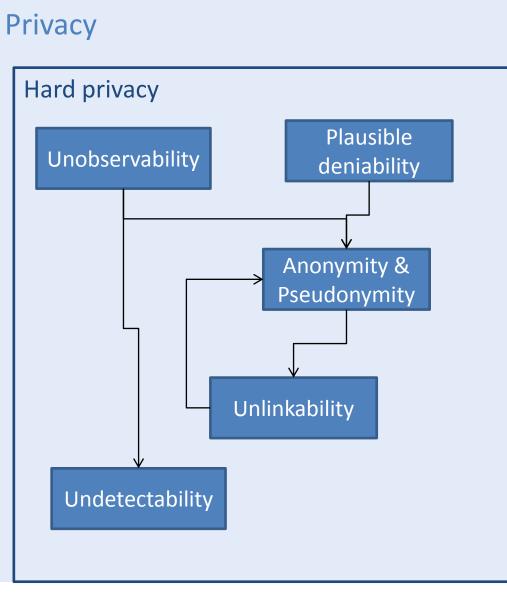

Unobservability

undetectability + anonymity of subjects involved in the IOI even against the other subjects involved in that IOI

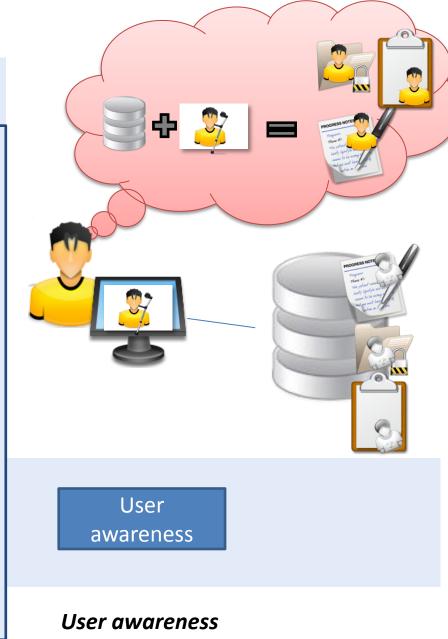

Undetectability & Unobservability

- Undetectability: The attacker cannot sufficiently distinguish whether it exists or not (Pfitzmann)
- Unobservability: undetectability + anonymity of subjects involved in the IOI even against the other subjects involved in that IOI (Pfitzmann)
- Hiding user activity
- Examples:
 - Impossible to see whether someone is accessing a web page
 - Impossible to know whether an entry in a database corresponds to a real person
 - Impossible to distinguish whether someone or no one is in a given location

 \longrightarrow requires

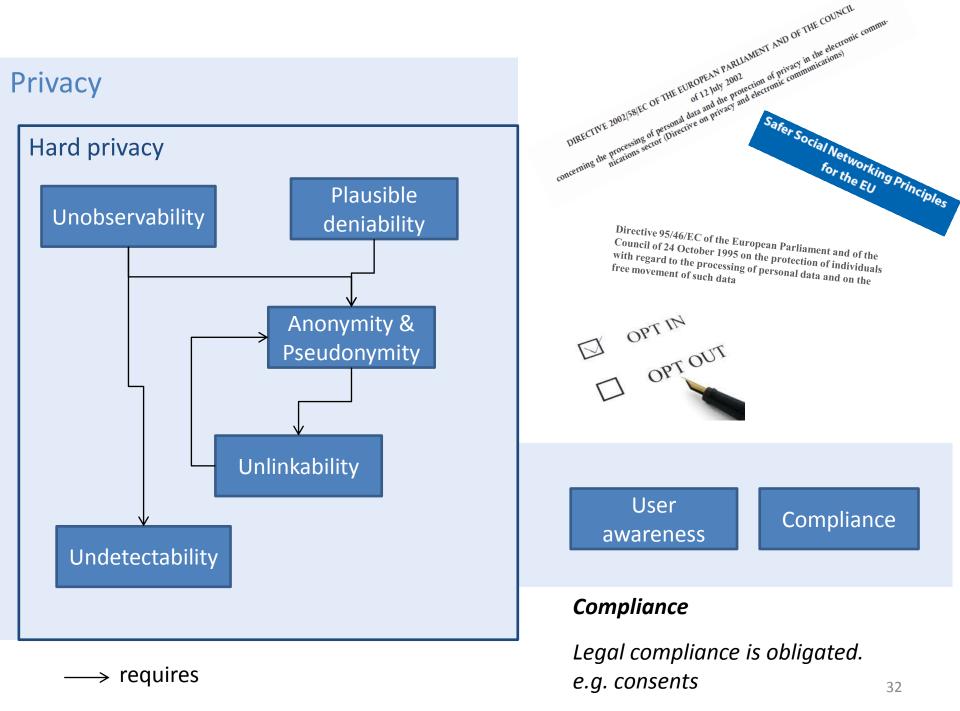

Users are aware of the consequences of sharing information 30

Content Awareness

- Users should be made aware of the consequences of sharing information
- Suggested solution: Feedback & awareness tools

Policy & Consent compliance

- Policies
 - Coorporate
 - Privacy

Openness to users
 + control

Policy & Consent compliance

- Legal compliance is obligated
 - E.g. European Data Protection Directive
 - fair and lawful processing
 - Consent
 - purpose specification
 - minimality
 - minimal disclosure

- information quality
- data subject control
- sensitivity
- information security

Compliance example: User consent

- *personal data* = any information relating to an identified or identifiable natural person ("data subject")
- Sensitive data = personal data revealing racial or ethnic origin, political opinions, religious or philosophical beliefs, trade-union membership, and the processing of data concerning health or sex life
- Processing of **sensitive data** *prohibited* unless
 - the processing is necessary for the protection of the vital interests of the data subject,
 - the processing is necessary for purposes of preventive medicine, medical diagnosis, provision of care or treatment or
 - the data subject has given his explicit, written consent to the processing of the data
 - ...(art. 7)

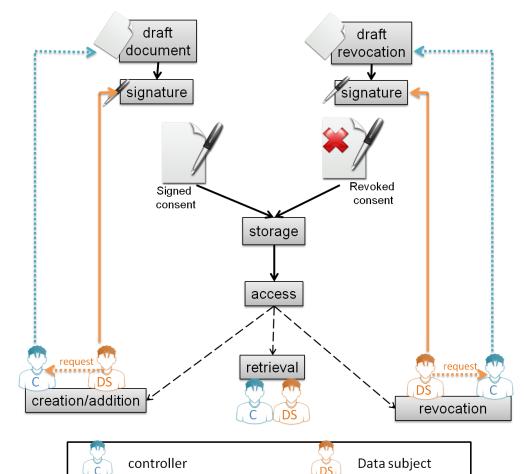

User consent

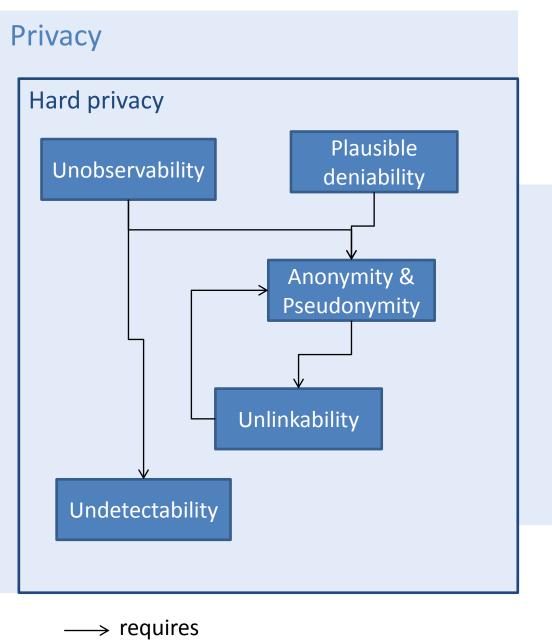

Legal requirements

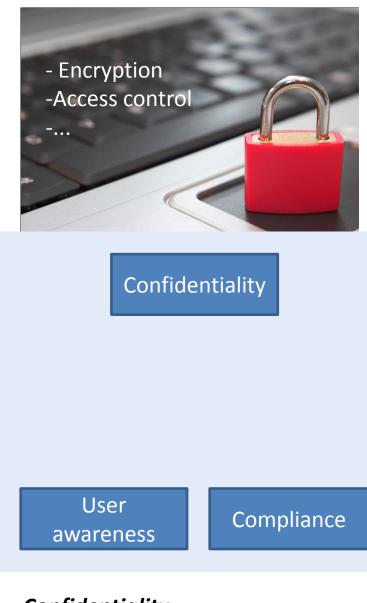

- Informed
- Freely given
- Specific

Consent structure

- Data subject
- •Controller
- •Receiver
- •Types of data
- •Action (Upload or share)
- •Purpose of sharing
- Type of consent (opt-in/opt-out)Revoked
- •(Context (e.g., "emergency"))
- •(Location)

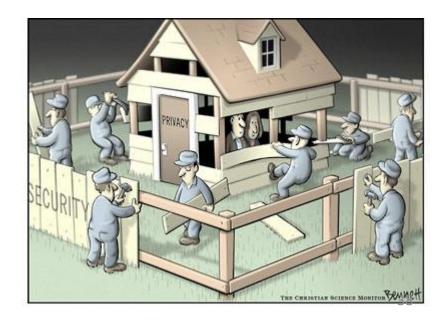

Confidentiality

authorized restrictions on information access and disclosure₃₇

Confidentiality

- Preserving authorized restrictions on information access and disclosure, including means for protecting personal privacy and proprietary information (NIST)
- Security property

Confidentiality: example

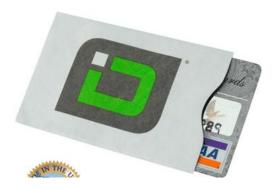

Problem: Electronic pickpocketing

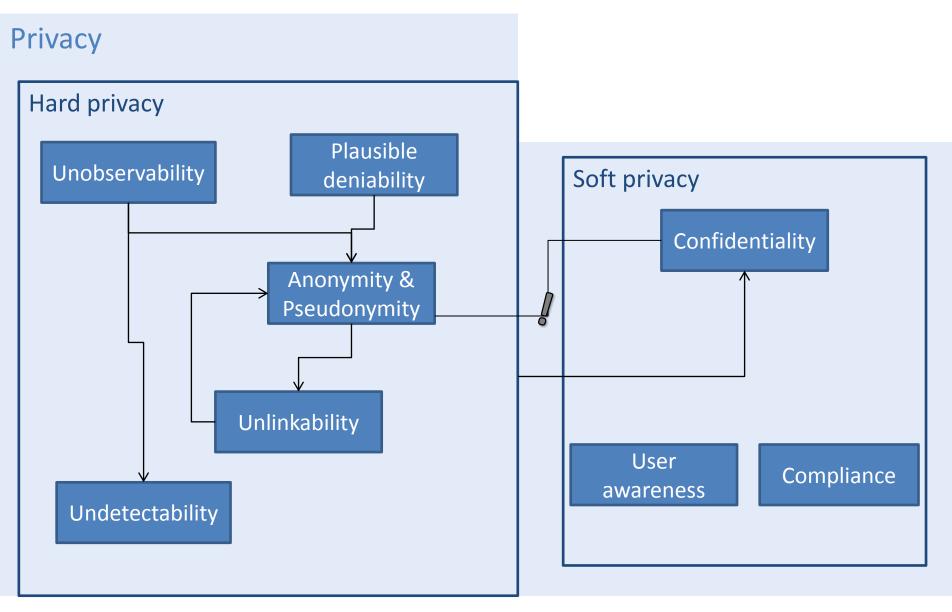

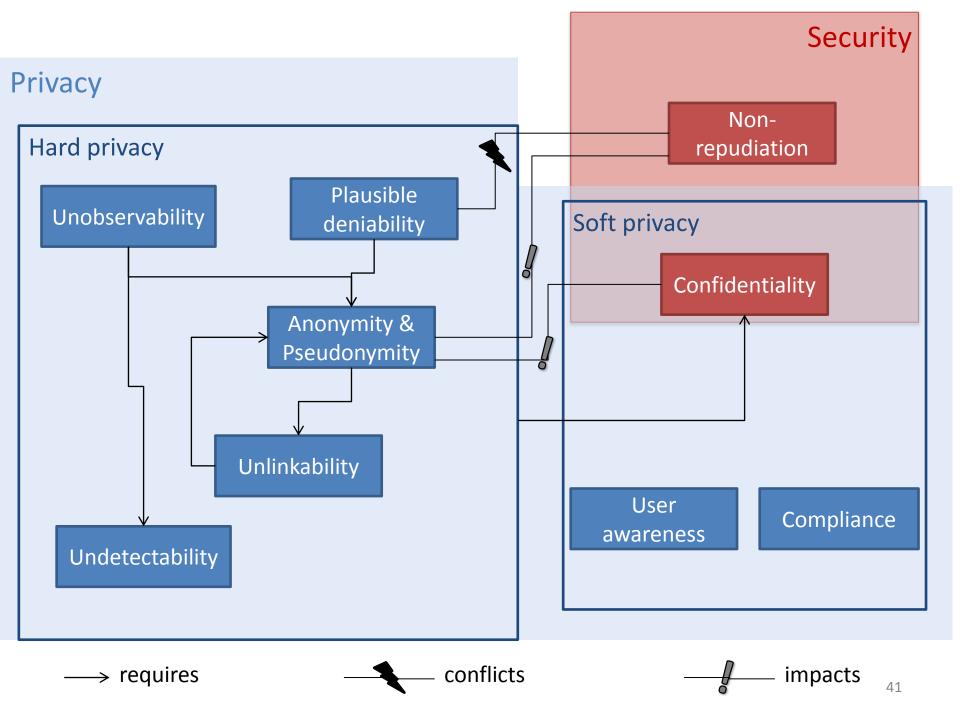

Solution: Confidentiality

 \longrightarrow requires

_____ impacts 40

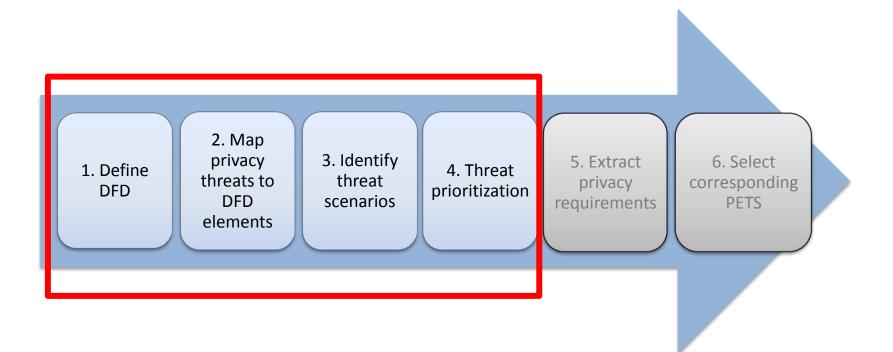

LINDDUN - Privacy threat analysis

PRIVACY METHODOLOGY

Integrating privacy in the system

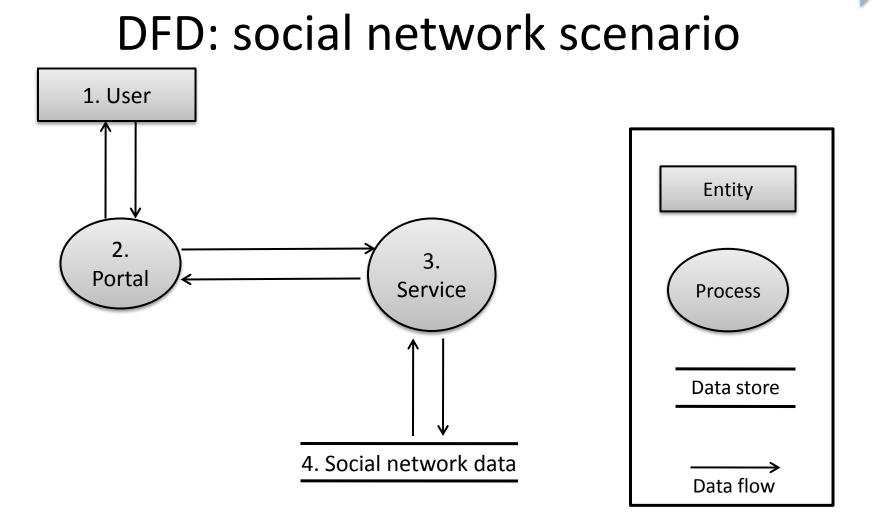

- Not straight-forward
- Should be part of Software development lifecycle
- Methodology based on STRIDE

- Step 1
 - Create the DFD diagram (assets)
- Step 2
 - Map LINDDUN to DFD element types
- Step 3
 - Refine threats via threat tree patterns
 - Document assumptions
 - Document the threats with template
- Step 4
 - Assign priorities

- Step 1
 - Create the DFD diagram (assets)
- Step 2
 - Map LINDDUN to DFD element types
- Step 3
 - Refine threats via threat tree patterns
 - Document assumptions
 - Document the threats with template
- Step 4
 - Assign priorities

LINDDUN privacy threats

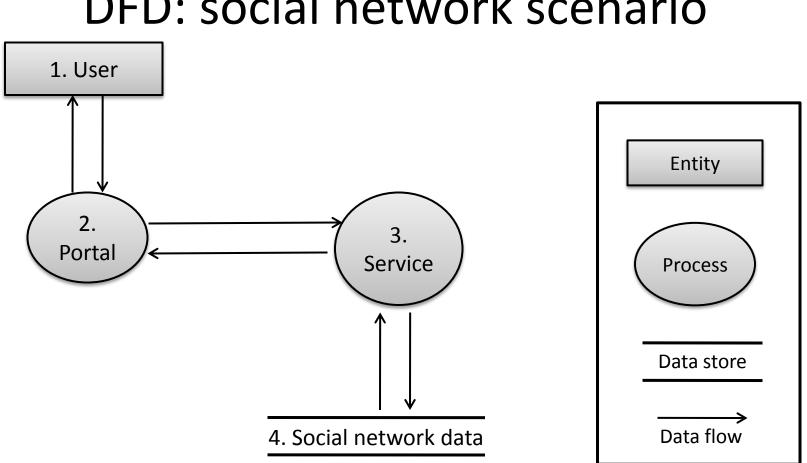

- Linkability
 - Sufficiently distinguish whether 2 IOI are linked or not
- Identifiability
 - Possible to identify the subject within a set of subjects
- Non-repudiation
 - Possible to gather evidence to counter the claims of the repudiating party
- Detectability
 - sufficiently distinguish whether IOI exists or not
- Disclosure of Information
 - Exposal of information to individuals who are not suppose to have access to it
- Unawareness of the content
 - user is unaware of the information he is supplying to the system
- Noncompliance of policy/consent
 - System is not compliant with its advertised policies/consents

Mapping threats to DFD

	Linkability	Identifiability	Non-repudiation	Detectability	Information Disclosure	Content Unawareness	Policy & Consent Non-compliance
Data store	Х	X	Х	Х	Х		X
Data flow	Х	Х	Х	Х	Х		X
Process	Х	X	Х	Х	Х		X
Entity	Х	X				Х	

DFD: social network scenario

Mapping Example scenario

	Threat target	L	I	N	D	D	U	N
Data store	Social network db	Х	Х	Х	Х	Х		Х
Data flow	User data stream (user- portal)	Х	Х	Х	Х	Х		Х
	Service data stream (portal- service)	X	X	Х	X	X		Х
	DB data stream (service – DB)	X	X	Х	X	X		Х
Process	Portal	X	X	Х	X	Х		Х
	Social network service	Х	Х	Х	Х	Х		Х
Entity	User	Х	Х				Х	

- Step 1
 - Create the DFD diagram (assets)
- Step 2
 - Map LINDDUN to DFD element types
- Step 3
 - Refine threats via threat tree patterns
 - Document assumptions
 - Document the threats with template
- Step 4
 - Assign priorities

1. DFD 2. Mapping 3. threat 4. prioritization

Assumptions

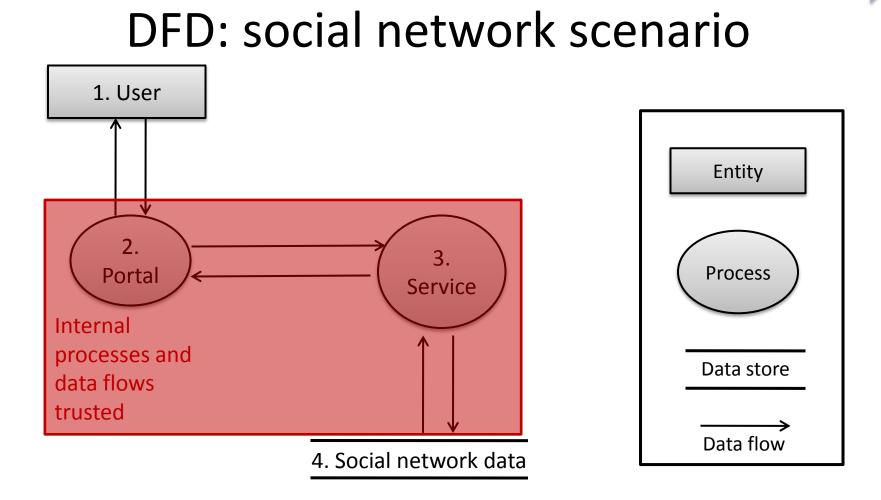

- Assumptions are explicit or implicit choices to trust an element of the system (e.g., human, piece of software) to behave as expected
- The privacy analyst trusts the assumption to be true
- These assumed properties or assertions act as domain restrictions, i.e., they restrict the domain in some way

Assumptions

- When adding DFD elements, the number of threats grows exponentially
 - Limit by making assumptions
- Example: assumptions for Social network 2.0:
 - 1. Internal DFD elements are trustworthy.
 - A. trust the processes and data flows in the back-end system.
 - B. do not trust the user and its communication with the portal or the data store containing all the user's information.
 - 2. non-repudiation and detectability threats are considered irrelevant for social networks. (based on threat trees)
 - 3. non-compliance threats are not specific to a specific DFD element, but are applicable to the entire system

Impact assumptions on example scenario

4.

prioritization

1. DFD

2. Mapping

	Threat target	L	I	N	D	D	U	Ν
Data store	Social network db	1	4	Х	Х	7		10*
Data flow	User data stream (user- portal)	2	5	Х	Х	8		10*
	Service data stream (portal- service)	Х	Х	Х		Х		10*
	DB data stream (service – DB)	Х	Х	Х	Х	Х		10*
Process	Portal	Х	Х	Х		Х		10*
	Social network service	Х	Х	Х	Х	Х		10*
Entity	User	3	6				9	56

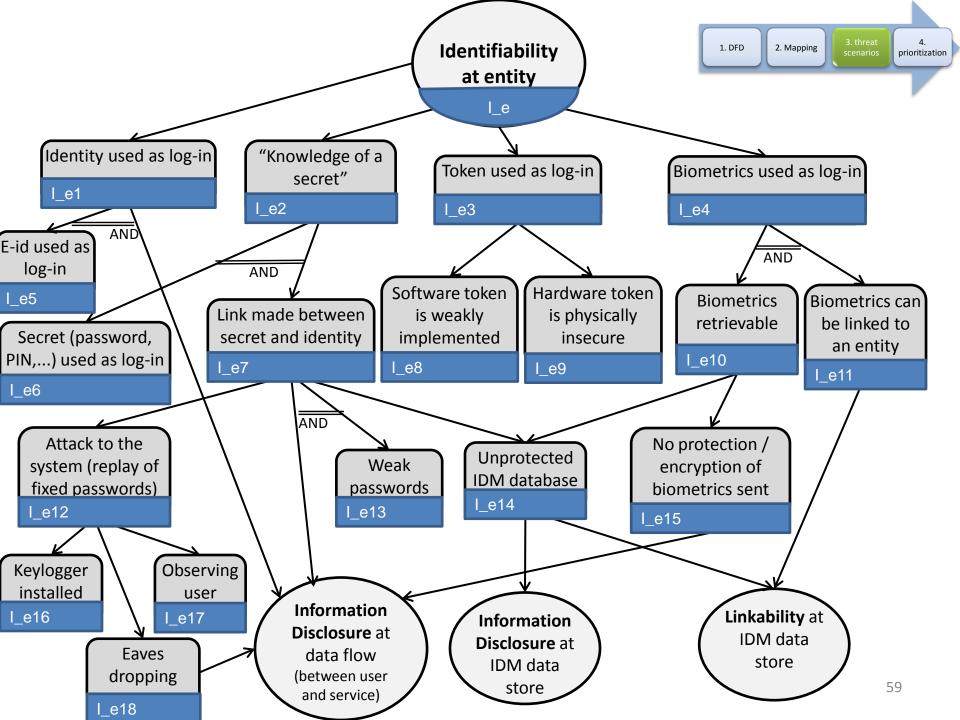

- Step 1
 - Create the DFD diagram (assets)
- Step 2
 - Map LINDDUN to DFD element types
- Step 3
 - Refine threats via threat tree patterns
 - Document assumptions
 - Document the threats with template
- Step 4
 - Assign priorities

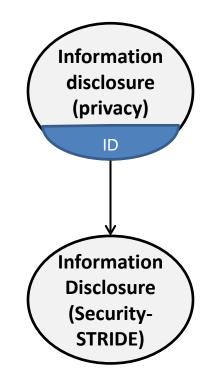

Privacy threat tree patterns

- Illustrate the most common attack patterns
- Used to determine threat applies to system

- Note:
 - Do not limit your analysis to these trees

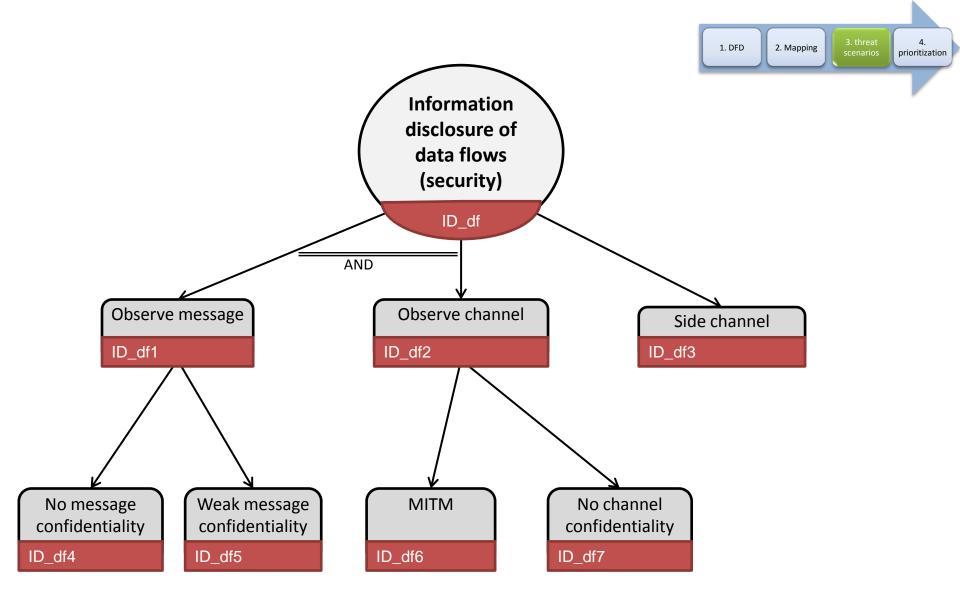

STRIDE revisited

- Systematic approach for security threat identification
- Spoofing, Tampering, Repudiation, Information disclosure, Denial of service, Elevation of privilege

- Step 1
 - Create the DFD diagram (assets)
- Step 2
 - Map LINDDUN to DFD element types
- Step 3
 - Refine threats via threat tree patterns
 - Document assumptions
 - Document the threats with template
- Step 4
 - Assign priorities

Threat description Inspired by Misuse Cases template

- ID & Title
- Summary
- Misactor profile
- Basic path
- Consequence

- Leaf node(s)
- Root node(s)
- DFD element(s)
- Remarks

In your report

Mention the threats in the order you found them

Threat description Example (naive) 1/3

- ID & Title
 - T01 . Identify users of the social network system
- Summary
 - A misactor gains access to the "secret" sent by the user to log-in and deduces the user's identity from it
- Misactor profile
 - skilled outsider

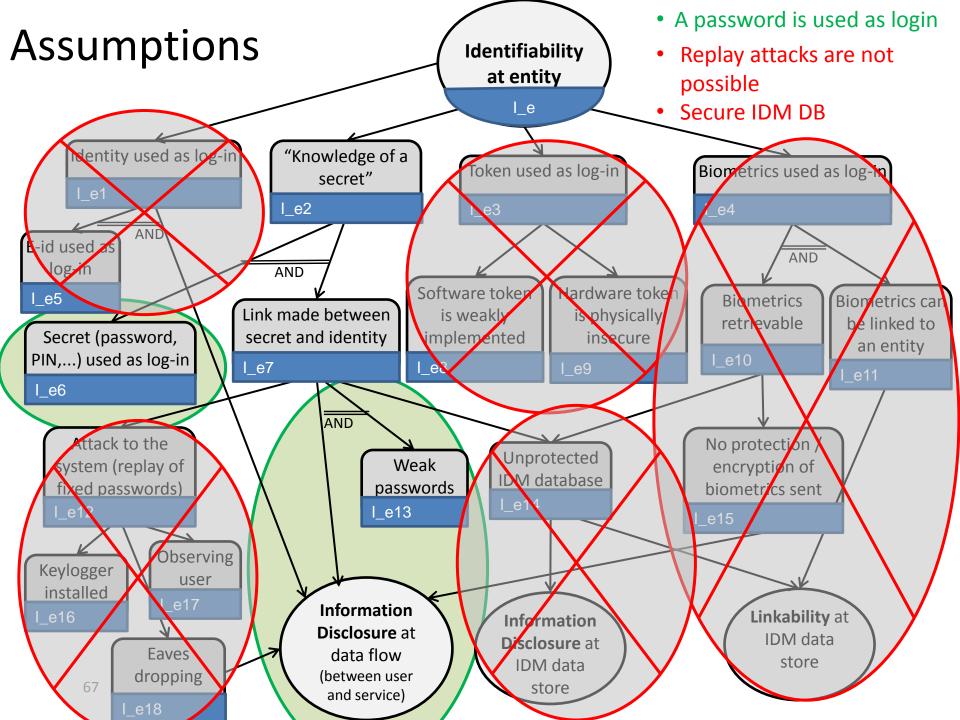

Threat description Example (naive) 2/3

Basic path

- 1. The misactor gains access to the data flow between the user and the portal
- 2. The data contains the user's password
- The misactor can directly link the password to the user due to weak password use (e.g. initials + birthdate)

Consequence

- The user's identity is compromised

Threat description Example (naive) 3/3

- Reference to leaf node(s): l_e6, l_e13
- Reference to root node: I_e
- DFD element: User
- Remarks:
 - the data flow between the user and the portal is susceptible to information disclosure threats (assumption 1B). This threat is described in T06.
 - A password is used as log-in (Assumption 4)
 - Replay attacks are not considered a threat (Assumption 5)
 - The IDM database is considered secure (Assumption 6)

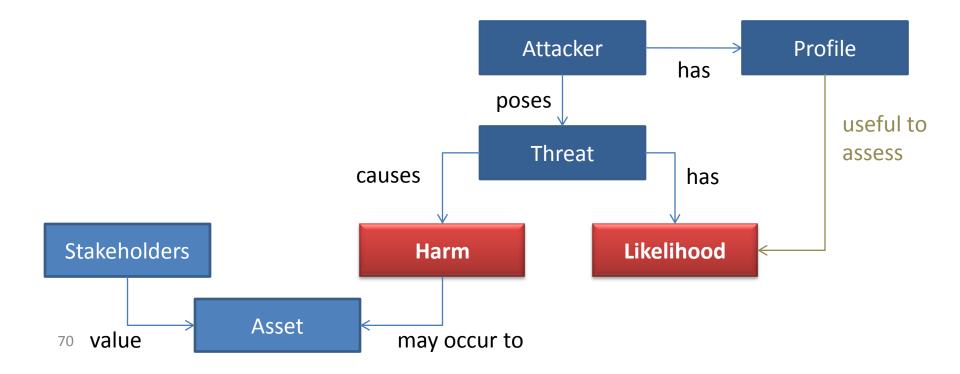

If these assumptions do not hold, the threat tree leaf nodes will result in additional threats

- Step 1
 - Create the DFD diagram (assets)
- Step 2
 - Map LINDDUN to DFD element types
- Step 3
 - Refine threats via threat tree patterns
 - Document assumptions
 - Document the threats with template
- Step 4
 - Assign priorities

The role of risk

Risk is a function of the likelihood of a threat and the severity of its impact on the organization
 R = f(likelihood , impact)

Suggested reading

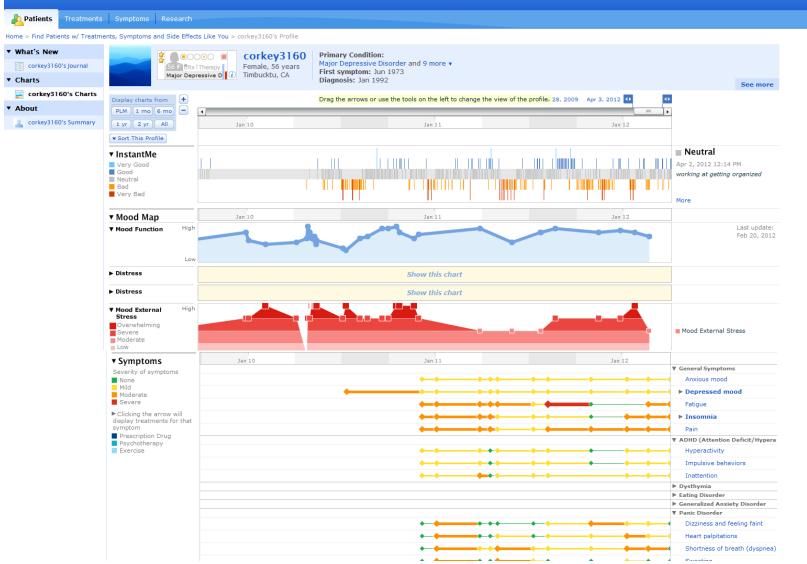

- Privacy
 - Pfitzmann & Hansen (2010): A terminology for talking about privacy by data minimization: Anonymity, Unlinkability, Undetectability, Unobservability, Pseudonymity, and Identity Management
 - defines anonymity, pseudonymity, undetectability, unobservability, unlinkability
 - Guerses (2010): Multilateral Privacy Requirements Analysis in Online Social Network Services (PhD thesis)
 - section 2.2 (pg. 22-32) provide an interesting overview of privacy. Especially interesting for the following concepts: *confidentiality, feedback and awareness*
 - Guarda and Zannone (2008): Towards the development of privacy-aware systems
 - for those interested in the legal aspects of privacy
 - summarize the privacy principles from a legislation perspective, as it is clearly also important that a system is compliant with law, policies, and user consent (*policy and consent compliance*)
- Methodology
 - LINDDUN: a privacy threat analysis framework
 - http://people.cs.kuleuven.be/~kim.wuyts/ERISE/LINDDUN.pdf

EXAMPLE – PATIENT COMMUNITY SYSTEM

LINDDUN - Privacy threat analysis

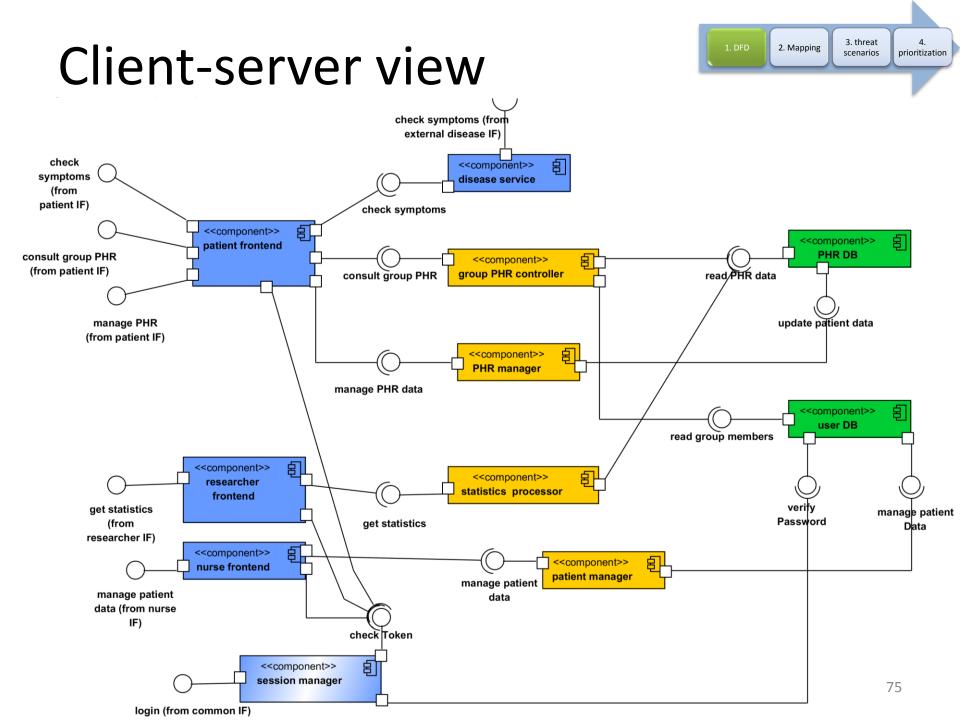

Existing patient communities

patientslikeme®

Patient communities case study

- Patient
 - Store personal health data (PHR)
 - Retrieve (pseudonymized) PHR from other patients (group members) with same condition
 - Retrieve trustworthy information on diseases and treatments (from external service)
- Nurse
 - Add users and manage groups
- Researcher
 - Retrieve (anonymized) PHR data to use in analysis

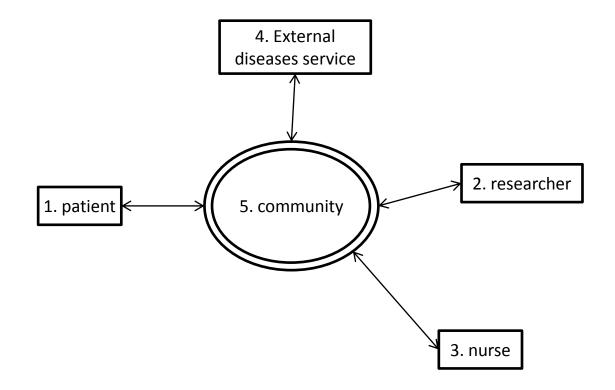

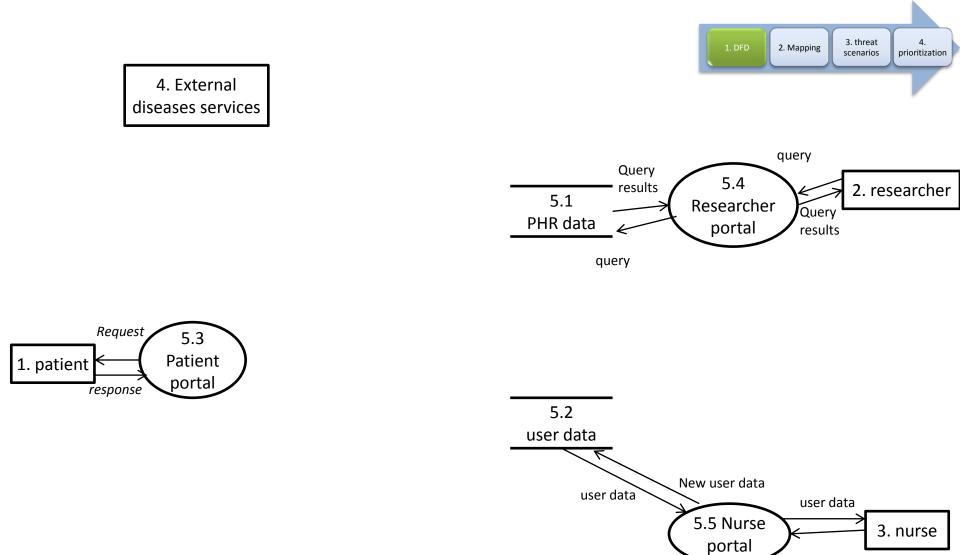

LINDDUN Methodology

- Step 1
 - Create the DFD diagram (assets)
- Step 2
 - Map LINDDUN to DFD element types
- Step 3
 - Refine threats via threat tree patterns
 - Document assumptions
 - Document the threats with template
- Step 4
 - Assign priorities

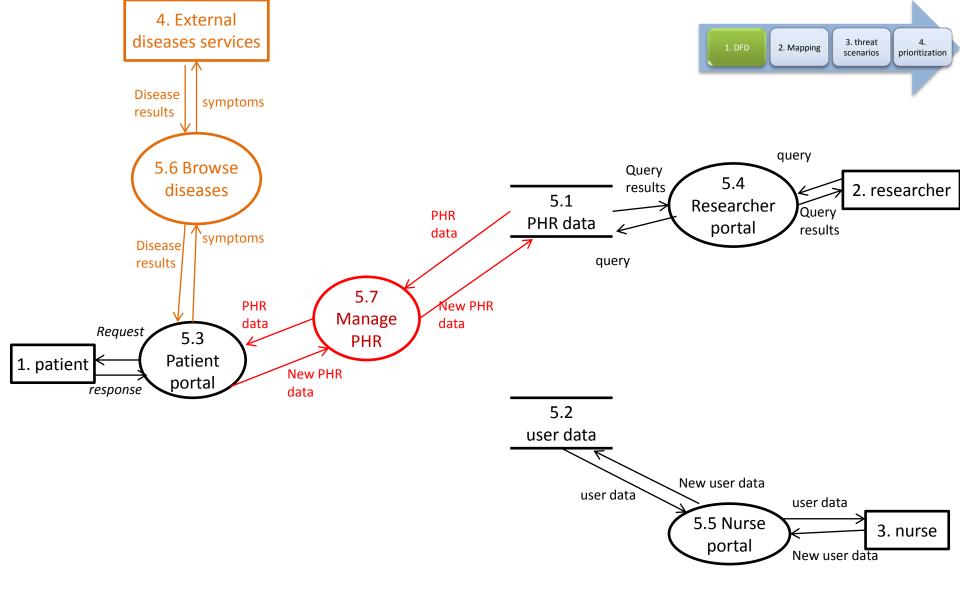

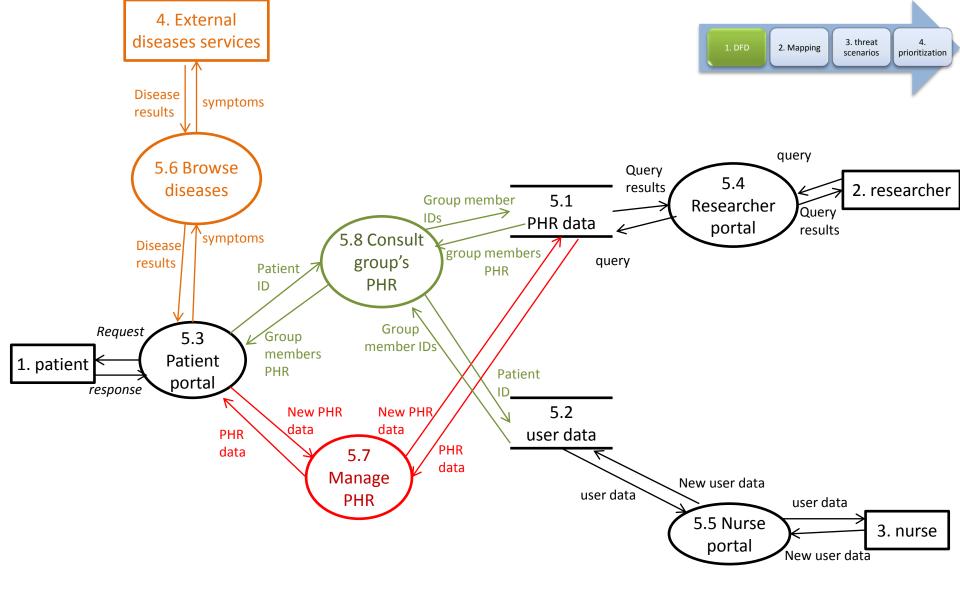

DFD level 0

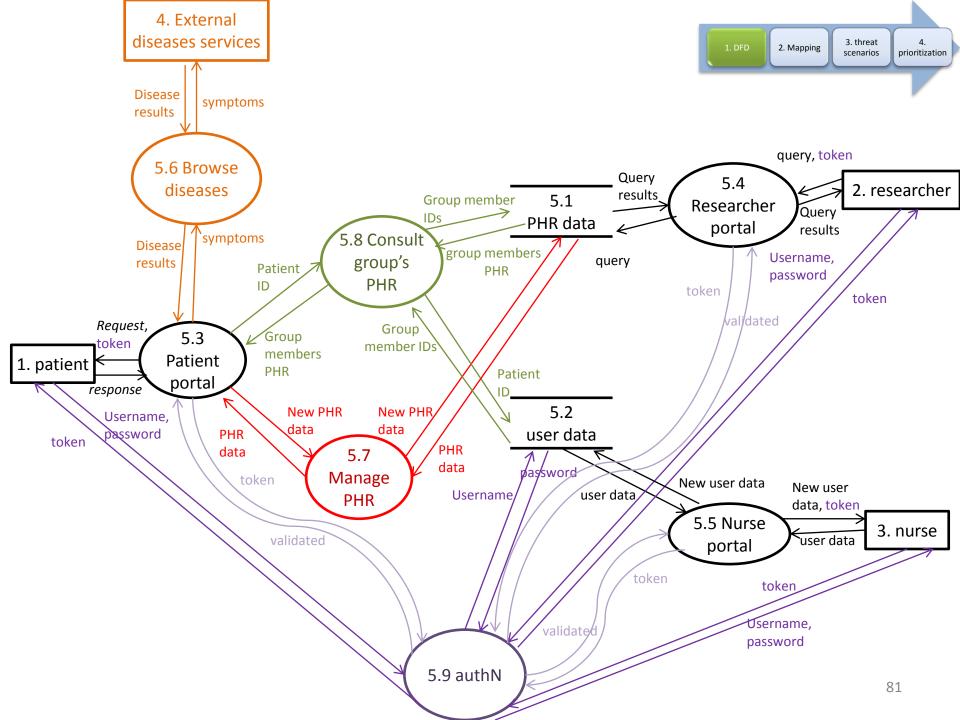

New user data

LINDDUN Methodology

- Step 1
 - Create the DFD diagram (assets)
- Step 2
 - Map LINDDUN to DFD element types
- Step 3
 - Refine threats via threat tree patterns
 - Document assumptions
 - Document the threats with template
- Step 4
 - Assign priorities

Mapping threats to DFD

LINDDUN Methodology

- Step 1
 - Create the DFD diagram (assets)
- Step 2
 - Map LINDDUN to DFD element types
- Step 3
 - Refine threats via threat tree patterns
 - Document assumptions
 - Document the threats with template
- Step 4
 - Assign priorities

 1. DFD
 2. Mapping
 3. threat scenarios
 4. prioritization

General assumptions

- 1. all internal processes are only susceptible to insider threats, as we consider the back-end sufficiently protected against outsider threats. We will therefore combine the process threats and examine only one, as the threats apply to all of them
- 2. all data flows between internal processes and between internal processes and internal data stores are only susceptible to insider threats, as we consider the back-end sufficiently protected against outsider threats. We will therefore combine the data flow threats and examine only one, as the threats apply to all of them
- 3. data flows between an entity and a process are not considered trusted (as it involves transactions of an external entity to and from a trusted process over an insecure communication line)
- 4. data stores are not considered confidential, as no access control system is present

Positive assumptions can help understand reasoning

General assumptions

- 5. No non-repudiation threats exist in the system, as the data flows, processes and data stores do not require plausible deniability
- detectability is not considered a threat for this specific system. The privacy concerns of this system are all focused on the data itself, not on the detectability of it
- 7. non-compliance is an important threat, however, it is not specific to one part of the system, but poses to the system as a whole. We will therefore not make a distinction between the different DFD elements for this threat.

4.

prioritization

1. DFD 2. Mapping 3. threat 4. prioritization

Assumptions

- 8. Identifiability of entities (researchers, nurses, patients or the external service) is not considered a threat, as all entities should have their own unique (long-term) identifier and there is no need to hide the entity's identity. Knowing that an entity is using the community service is not considered an issue.
- 11. Linkability of entities (sensors, cardiologists, nurses, or patients) is not considered a threat, as all entities should have their own unique (long-term) identifier and there is no need to hide the entity's identity. Knowing that an entity is using the community service is not considered an issue.

	External disease service (4)	Х	Х				Х	

1. DFD 2. Mapping 3. threat 4. prioritization

Assumptions

- 14. Linkability and identifiability do not pose a threat to the data flows between entities (patient, nurse, and researcher) and (portal) processes because of assumptions 8 and 11
- 9. Identifiability of the data flow only poses a threat to one specific data flow: 5.6 ->4 (browse diseases to external disease services), as the external service should not be able to identify the patient that is using this disease browsing service.
- 10. Linkability of the data flow to the external disease service (5.6 -> 4) is the only linkability threat to data flows in the patient community system. Although less likely, when the patient identifiers are replaces by pseudonyms, linking the different symptoms (of different searches) together can still result in an identifiability threat
- 15. Linkability and identifiability do not apply to internal data flows as knowing that 2 requests belong to the same user, or knowing who made a request does not violate the patient's privacy. The patient's privacy is only violated when the content of the communication is revealed (information disclosure threat)
- 16. Linkability and identifiability do not apply to internal processes as knowing that 2 actions belong to the same user does not violate the patient's privacy. The patient's privacy is only violated when the content of the action is revealed (information disclosure threat)

		L	I.	N	D	D	U	N

Entity	Patient (1)	Х	Х				Х	
	Researcher (2)	Х	Х				Х	
	Nurse (3)	Х	Х				Х	98
	External disease service (4)	Х	Х				Х	

Assumptions

- 12. Information disclosure between the external disease service and the browse disease process does not pose a threat, as it does not contain any sensitive or personal information
- 19. Content unawareness only applies to the patient, as the researcher does not add any information, a nurse only registers patients, and the external disease service does not directly input any data
- 17. Identifiability and linkability are applicable to both data stores, and will therefore be examined in a combined fashion

	External disease service (4)							101

LINDDUN Methodology

- Step 1
 - Create the DFD diagram (assets)
- Step 2
 - Map LINDDUN to DFD element types
- Step 3
 - Refine threats via threat tree patterns
 - Document assumptions
 - Document the threats with template
- Step 4
 - Assign priorities

Linking community data

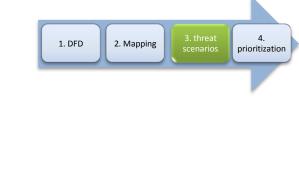

- Assumption: Identifiability and linkability are applicable to both data stores, and will therefore be examined in a combined fashion
- linking PHR data

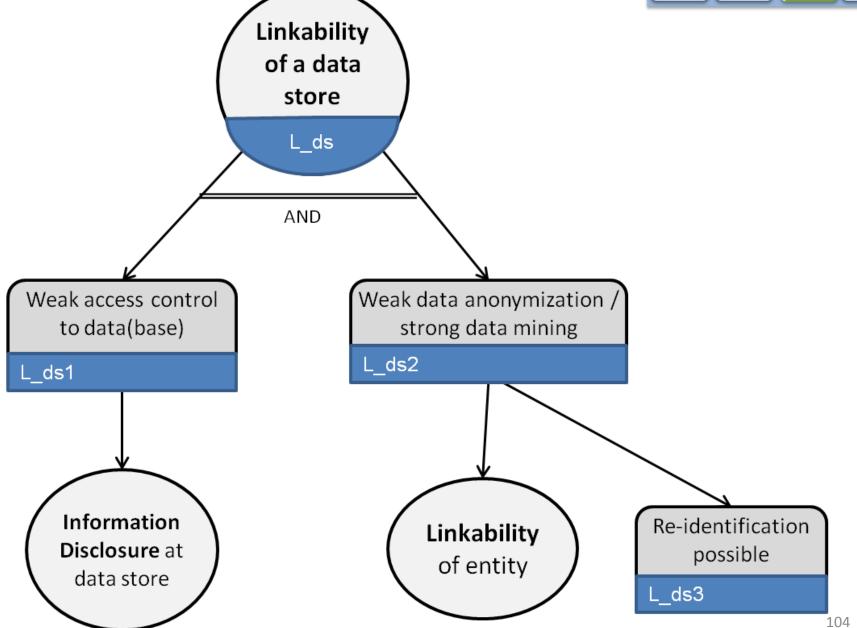

- Applies also to user data

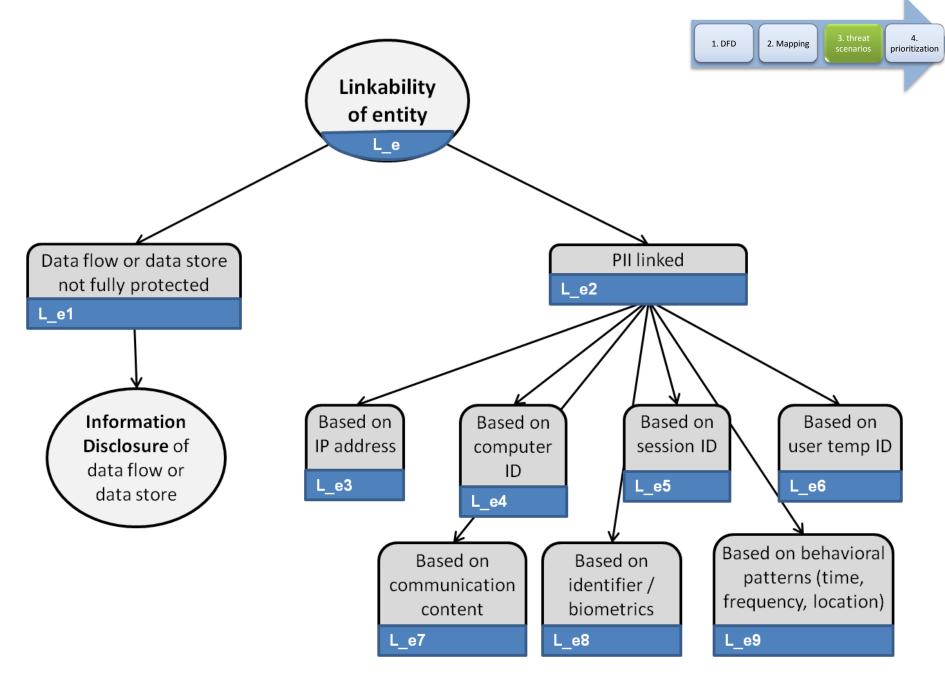

4

prioritization

1. DFD

T01 - Profiling PHR data (linking)

Summary: A researcher or other insider with malicious intent links PHR data (or user data) Primary mis-actor: unskilled insider (authenticated user, e.g. researcher) Basic path:

- bf1. The misactor performs a set of targeted queries on the PHR data or user data store and retrieves very detailed results
- bf2. The misactor links the results of the queries together (e.g. based on medication which is usually combined, medical conditions which occur together, or pseudo-identifiers like street and age)
- **Consequence**: By combining the query results, the misactor has access to more information about the patient than anticipated
- Reference to threat tree node(s): L_ds2, L_e2

Parent threat tree(s): L_ds, I_ds

DFD element(s): 5.1 PHR data, 5.2 user data

Remarks:

- r1. This threat can be used as precondition for the identifiability threat at the data store (T03 Identifying a patient from his PHR data)
- r2. This threat was inspired by L_ds2 and L_e2, however none of L_e2's leaf nodes matched
- r3. The (weak) access requirement (L ds1) is fulfilled because the misactor is an insider who has access to the database
- r4. Although this threat mainly describes the PHR data case, it also applies to the user data store (assumption 4)

4.

prioritization

1. DFD

Linking community data

- Assumption: Identifiability and linkability are applicable to both data stores, and will therefore be examined in a combined fashion
- linking PHR data

- Applies also to user data

• Linking PHR data to user data

4

prioritization

1. DFD

1. DFD 2. Mapping

at 4. ios prioritization

TO2 - Linking PHR data to user data

Summary: The administrator or other insider with access to both the PHR data store and user data store is able to link the data from both databases (and sell this information to advertisers, insurance companies, etc.)

Primary mis-actor: unskilled insider with access to both data stores

Basic path:

- bf1. The misactor retrieves information from both the PHR data store and the user data store
- bf2. The misactor links both sets of data (e.g. based on a shared foreign key)
- **Consequence:** The combined set of data contains (possibly sensitive) personal identifiable information and especially poses a privacy threat when the misactor sells the information (e.g. to a company selling medication, to the patient's insurance company, etc.)

Reference to threat tree node(s): L_ds2, L_e6

Parent threat tree(s): L_ds, I_ds

DFD element(s): 5.1 PHR data, 5.2 user data

Remarks:

- r1. The L_ds1 requirement of (weak) access is fulfilled, as this threat only involves insiders who have access to the data stores
- r2. The linkability of entity leaf node L_e6, indicating linkability based on the user's temporary ID inspired to this data store linkability threat

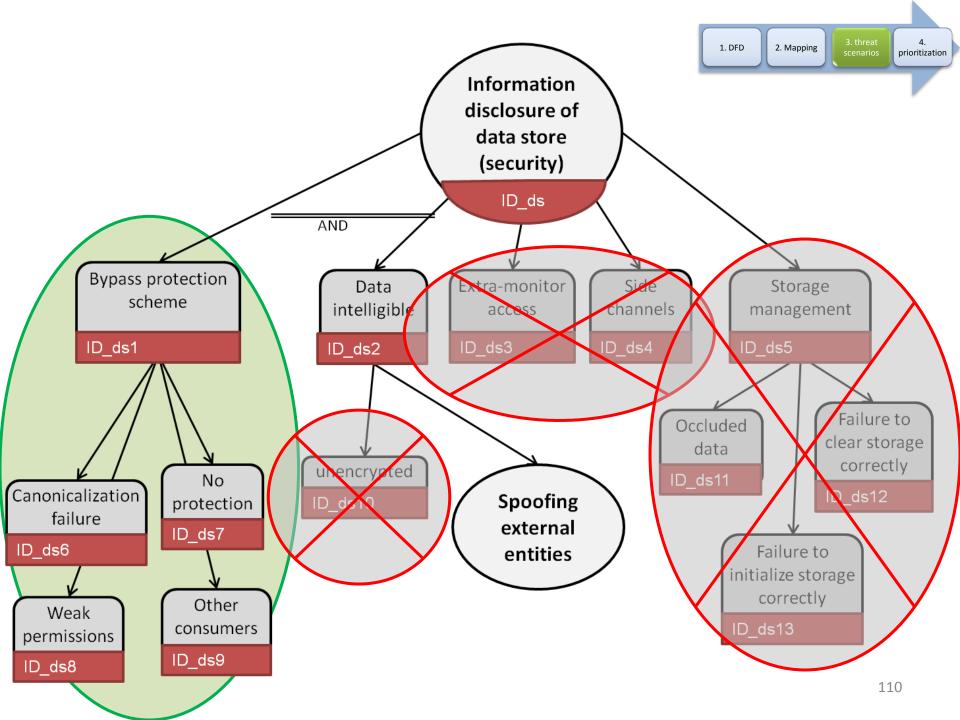

Information disclosure of community data

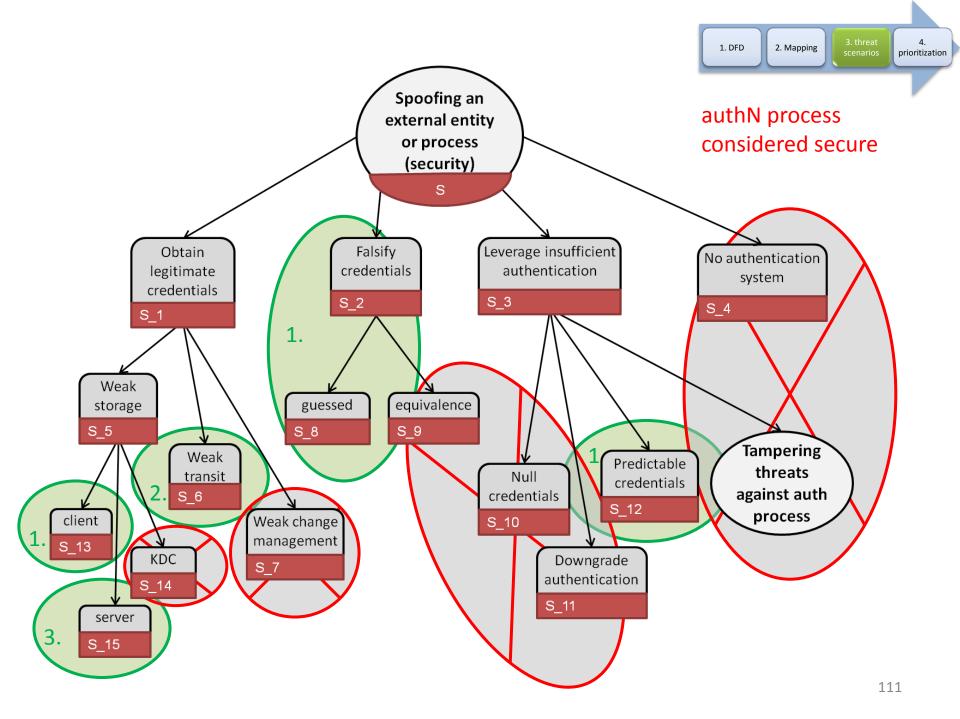

1. DFD

2. Mapping

prioritization

- no access control system is present (assumption 4)
- We assume that the data stores are sufficiently protected and that side-channel attacks, extra-monitor and bad storage management are not possible (assumption 20)

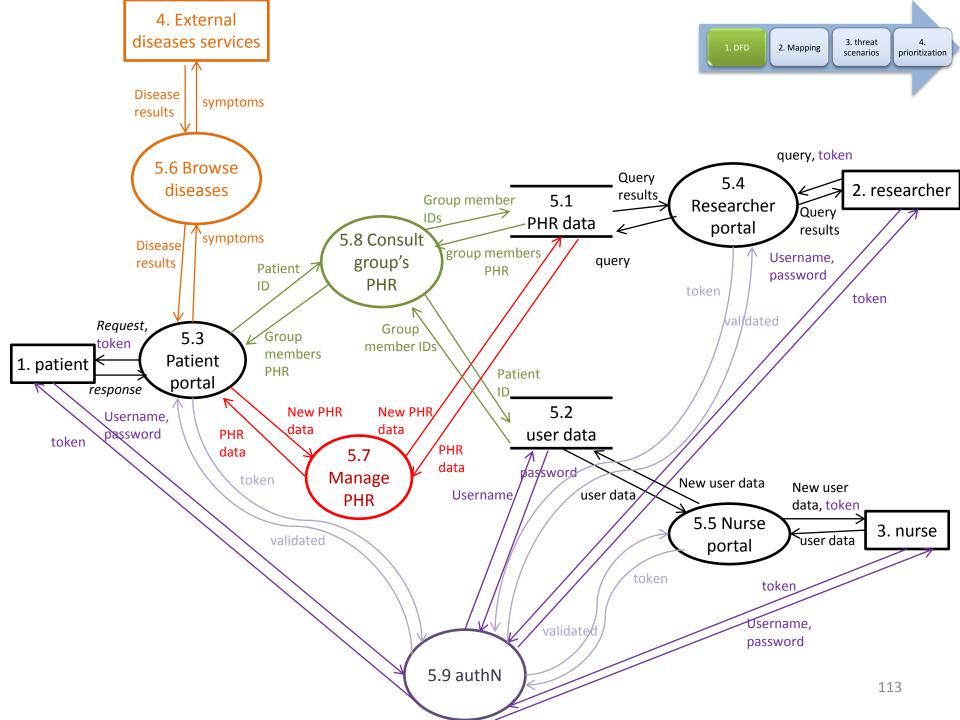

Spoofing users (patients, researchers, nurses)

- Spoofing by falsifying credentials
- Spoofing by eavesdropping communication
 - Information disclosure of transmitted credentials
 - Information disclosure of transmitted session token
- Spoofing because of weak credential storage
 Information disclosure of community data

4

prioritization

spoofing external disease service

Spoofing external disease service

Summary: The external disease service is spoofed (e.g. by a competitor or a advertising company for medication)

Primary mis-actor: Skilled outsider

Basic path:

- bf1. The misactor pretends to be the disease service
- bf2. The community browse service contacts the spoofed disease service with symptoms
- bf3. The misactor returns false information
- **Consequence:** The patient community system returns false disease information to the patient which has an impact on the system's reputation (as one of the benefits of the provided service is the trustworthiness of the information)

Reference to threat tree node(s): S 4

Parent threat tree(s): S

DFD element(s): 4. external disease service

This is **NOT** a **privacy** threat.

1. DFD

2. Mapping

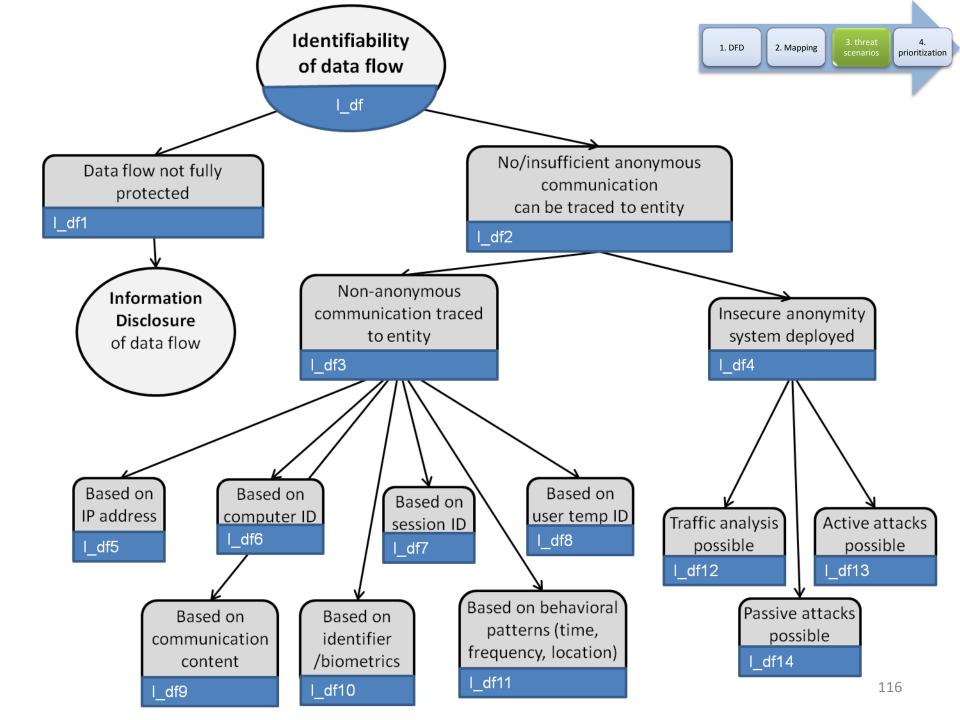

prioritization

It is a security threat (against integrity) And should not be included

1. DFD 2. Mapping 3. threat 4. prioritization

External disease service

- Linkability & Identifiability of data flow
 - NOT during transit
 - When arrived at external disease service
 - Always information disclosure

1. DFD 2. Mapping 3. threat 4. scenarios prioritization

T12 - Identifiability of data sent to external disease service

Summary: The misactor extracts the patient's identity from the request and links it to the symptoms **Primary mis-actor:** unskilled insider/skilled outsider

Basic path:

- bf1. The patient searches diseases by providing his symptoms to the patient portal, which forwards the request (include the patient's identifiable information (e.g. SSN, address, etc.) to the external disease service
- bf2. The misactor intercepts the data flow (threat T10 Information disclosure of transmitted medical or personal data) or is (or has access to) the external disease service

Consequence: The misactor knows which patient has which symptoms

```
Reference to threat tree node(s): I_df1, I_df8
```

Parent threat tree(s): I_df

DFD element(s): data flow from browse service to external disease service (5.6 -> 4)

Remarks:

- r1. I_df1 requires an unprotected data flow, which is currently present (assumption 3) and misactor is receiver, thus assumption always applies
- r2. The different requests are traced back based on the transmitted (temporary/internal) user ID (I_df8)
- r3. The right branch of the tree (insecure anonymity system (I_df4)) and the other leaf nodes of the non-anonymous communication branch (I_df3) are not considered, as it is not the sender (browse service) whose identity should be protected, but the patient, who is not directly part of the data flow

Soft privacy

- Non-compliance of employees
- Non-compliance of management
- Missing consent system
- Patient unawareness
- Content inaccuracy

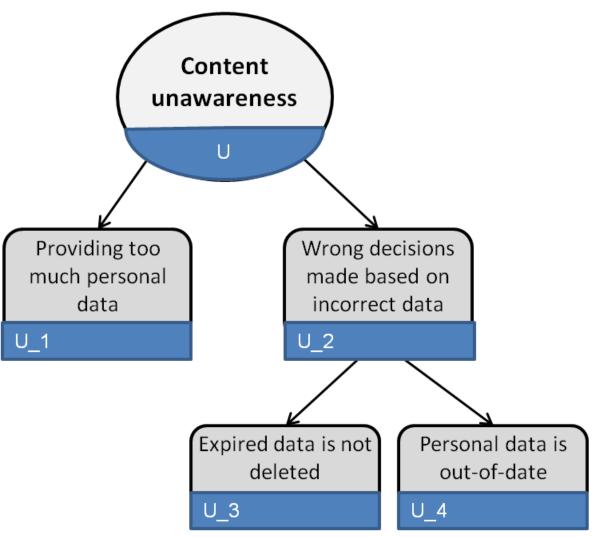

4

prioritization

1. DFD

2. Mapping

T19 - User unwareness

Summary: The user is unaware of the consequences of sharing information (e.g. by sharing too much information even anonymized data can reveal the user's identity)

Primary mis-actor: Management

Basic path:

- bf1. The management fails to add as requirement the need of notifications and warnings when the patients intends to upload sensitive and/or identifiable content (e.g. picture of his broken arm which also shows his face)
- bf2. The user adds information to the system which can easily identify him (e.g. a picture of himself) as he is unaware of the consequences
- bf3. Group members retrieve information and can still identify the pseudonymized user
- **Consequence:** When group members retrieve information, the identifiable information. The user's privacy is violated as he assumes that his information stays confidential and his identity will not be revealed

Reference to threat tree node(s): $\cup 1$

Parent threat tree(s): U

DFD element(s): 1 patient

Remarks:

- r1. This threat only applies to the patient (assumption 19)
- r2. The threat concerning inaccurate user information is described in T20 content inaccuracy

4.

prioritization

1. DFD

2. Mapping

				I	N	D	D	U	N
Data store	PHR data (5.1)		T01	т03			T04, T05, T06, T07		
	User data (5.2)	T02							
flow	Patient – portal flow (1 -5.3)				1		т09		
	Portal – patient flow (5.3-1)						T10		
	Researcher – portal flow (2-5.4)								
	Portal – researcher flow (5.4-2)								
	Nurse – portal flow (3-5.5)								
	Portal – nurse flow (5.5-3)								
	Disease service – browse diseases flow (4-5.6)								T16, T17,
	Browse disease – disease service flow (5.6-4)	T	11	T12					T18
22222	Patient portal - browse diseases flow (5.3-5.6)						T13		
	Patient – authN flow (1-5.9)						т08		
	authN - patient flow (5.9-1)								
	Research – authN flow (2-5.9)						,		
	authN flow – researcher (5.9-2)								
	Nurse – authN flow (3-5.9)								
	authN – nurse (3-5.9)								
process	Patient portal (5.3)						T14, T15		
Entity	Patient (1)							T19, T20	
	Researcher (2)								
	Nurse (3)							1	21
	External disease service (4)								

Information disclosure and identifiability of stored data violate privacy more than disclosure of "partial" transmitted data

Priorities

<u>High</u>

- T04 Information disclosure of patient community data
- T03 Identifying a patient from his PHR data
- T08 Disclosure of the transmitted log-in credentials
- T09 Disclosure of the transmitted session token
- T10 Disclosure of transmitted medical/personal information
- T05 Spoofing a user of the social network system by falsifying credentials
- T07 Spoofing a user of the social network system because of weak credential storage
- T06 Spoofing a user of the social network system by eavesdropping communication

Spoofing leads to information disclosure which is a high risk threat

<u>Medium</u>

- T12 Identifiability of data sent to external disease service
- T11 Linkability of symptoms sent to external disease service
- T01 Profiling PHR data (linking)
- T02 Linking PHR data to user data
- T18 Non-compliance management
- T17 Missing user consents
- T19 User unwareness

Data in system is purely informative, and not used for important decisions, thus impact of threat is low

<u>Low</u>

- T16 Non-compliance of employees
- T20 content inaccuracy
- T14 Information disclosure internal process
- T13 Disclosure of internal transmitted medical/personal information
- T15 Side channel information disclosure internal process

There is a trust relationship with the employees, thus likelihood of threats is low

Only partial data and patient deniability

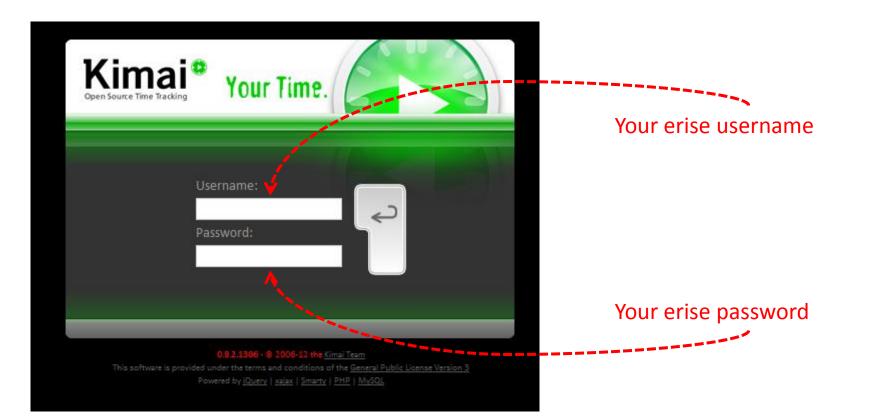

Linkability can lead to identifiability

Non-compliance can still have "part" in place + reputation 122

LINDDUN - Privacy threat analysis

Questionnaires

- Entry questionnaire
 - Before you start the working on the assignment
 - Understand your background
- Exit questionnaire
 - After you have turned in your report
 - Getting your feedback
- You can stay anonymous if so desired
- Please, fill in per student (not per team)
- Links are provided in the assignment

Online threat tree catalog

• Privacy threat trees are available online

• Login using your erise account

Your browsing activity is tracked
 Please, look at one page at the time

https://people.cs.kuleuven.be/~kim.wuyts/private/ERISE/

Report structure

- Follow structure of example report
 - DFD
 - Mapping
 - Threat elicitation
 - Prioritization
- (if required) latex templates can be used for
 - General structure of the document
 - Mapping table
 - Description of the threats
